(54) Title: ELASTOMERIC ARTICLE WITH FINE COLLOIDAL SILICA SURFACE TREATMENT, AND ITS PREPARATION

(57) Abstract: A surface-modified article is formed of an elastomeric matrix, such as a glove shape, and a plurality of fine silica particles affixed to at least a portion of the surface of the matrix, the outside surface in the case of the glove. The fine silica particles increase the coefficient of friction of the article surface. The fine silica particles may also be made electrically conductive, so that static charge at the surface of the article is dissipated. The silica particles are applied by mixing them into a coating composition, applying the coating composition to the surface of a mold, and solidifying a flowable elastomeric composition against the coated surface. The coating composition may include a coagulant or a parting agent.

WO 00/76332 A1

5                   ELASTOMERIC ARTICLE WITH FINE COLLOIDAL SILICA  
                    SURFACE TREATMENT, AND ITS PREPARATION

                    This invention, relates to elastomeric articles such as gloves, and  
                    their surface treatment to improve properties.

10

                    Elastomeric materials are used in many types of articles because of  
                    their rubbery properties. They elastically elongate up to hundreds of  
                    percent, and then return to or toward their original shape when released.  
                    Protective gloves used in medical procedures and manufacturing  
                    operations are examples of the application of elastomers. Elastomers may  
                    be either natural or synthetic.

15

20

                    Elastomeric articles are typically tacky to the touch when initially  
                    manufactured. The tackiness increases the difficulty in handling the glove  
                    during manufacture, packaging the glove for sale and shipment, and  
                    donning the glove by the user. Elastomeric gloves are usually processed  
                    to reduce their tackiness. Historically, the most common processing to  
                    reduce tackiness has been the application of a powder such as cornstarch  
                    to the surface of the glove during manufacture. The use of a powder is  
                    acceptable for many glove applications. A powder may not be used for  
                    other applications, such as for surgical gloves, because the powder may  
                    find its way into the surgical wound. A powder may not be used for some  
                    manufacturing operations where gloves are required, because the powder  
                    may fall into sensitive structures being fabricated. Powder-free processing  
                    techniques have been developed for such applications.

25

30

                    Another of the problems experienced with elastomeric gloves is that  
                    their outer surfaces may become slippery when they are wet, so that the  
                    user of the glove may find it more difficult to grasp objects in the gloved  
                    hand without losing the grip. This slipperiness problem is particularly  
                    troublesome for gloves treated by powder-free processing techniques,

5           because the very processing which reduces tackiness on the inside surface  
of the glove, thereby aiding donnability, also tends to modify the outside  
surface of the glove and reduce tackiness, thereby promoting loss of  
gripping power. Although efforts may be made to confine particular  
10           treatments to only the inside surface or the outside surface of the glove,  
these attempts have not been generally successful and have led to  
inconsistent results within lots of gloves.

          The friction of the outside surface of the glove may instead be  
increased with a pattern of shallow ridges or the like on the outside surface.  
These features reduce the sensitivity of feel for the user of the glove, which  
15           is unacceptable for many applications such as medical and sensitive  
manufacturing operations.

          There is a need for an approach to improving the friction of the outer  
surfaces of elastomeric gloves and the surfaces of other articles, which  
does not adversely affect other properties of the article and is consistent  
20           with powder-free manufacturing techniques. The present invention fulfills  
this need, and further provides related advantages.

### SUMMARY OF THE INVENTION

25           This invention provides a surface-modified elastomeric article, such  
as a glove, and a method for its manufacture. The approach of the  
invention increases the surface friction of the outside surface of the glove.  
The approach is fully consistent with the use of powder-free manufacturing  
techniques and in those cases meets governmental requirements for  
30           powder-free articles. The improved outside-surface friction is achieved  
without modifying the basic physical structure of the article, without loss of  
the existing advantageous properties of the article, and with little increased  
cost. The treatment to achieve improved surface friction on some surfaces  
of the article may be applied in conjunction with other treatments of other

5 surfaces of the article. For example, the outside surface of the glove may be treated to increase its friction, and the inside surface may be separately treated to improve its donnability without losing the increased friction on the outside surface. The mechanical properties of the basic glove are not sacrificed in order to attain improved donnability and grip retention. The surface modification of the article can also be made to increase the dissipation of static electrical charge, reducing the incidence of damage due to such static electrical charges. The processing approach leads to excellent consistency in batches of manufactured gloves.

10 In accordance with the invention, a surface-modified article comprises an elastomeric matrix having a surface, and a plurality of colloidal silica particles adhered to at least a portion of the surface of the matrix but not extending through the thickness of the matrix. The colloidal silica particles are affixed to the surface of the matrix, preferably without any separate binder material affixing the colloidal silica particles to the surface. In a preferred application, the elastomeric matrix is in the shape of a glove that receives the human hand therein. The matrix has an inside surface that contacts the human hand received within the hollow elastomeric glove shape, and an oppositely disposed outside surface. The colloidal silica particles are affixed to the outside surface of the glove.

25 The elastomer may be any operable material, such as natural latex, or a synthetic elastomer, such as styrene butadiene, neoprene, isoprene, nitrile, styrene-ethylene-butylene-styrene (S-EB-S), styrene-isoprene-styrene (S-I-S), or styrene-polybutydiene-styrene (S-B-S) rubbers. The colloidal silica particles desirably have a size of from about 10 nanometers to about 100 nanometers.

30 In one embodiment, the colloidal silica particles are themselves provided or treated so as to have some electrical conductivity. The electrical conductivity may be produced by depositing a partially conductive layer onto the surfaces of the particles, such as a thin layer of aluminum

5 chlorhydrate. The electrical conductivity of the partially conductive colloidal silica particles improves the electrostatic discharge (ESD) properties of the article, permitting static charge to dissipate more rapidly and completely than would otherwise be the case. Dissipation of static charge is an important requirement in many applications of elastomeric articles such as  
10 gloves, inasmuch as accumulated static charge in medical facilities or manufacturing plants may adversely affect treatments, instrumentation, and/or products.

The present invention also extends to a manufacturing method for preparing an article such as a glove. A method for making an elastomeric  
15 article comprises the steps of preparing a coating composition comprising a plurality of colloidal silica particles, providing a mold whose surface defines at least a portion of the surface of the elastomeric article, and applying the coating composition to a surface of the mold to achieve a coated surface. The method further includes contacting a flowable  
20 elastomer to the coated surface of the mold, allowing the flowable elastomer to coalesce against the coated surface, and separating the formed elastomer from the mold surface.

In the preferred embodiment, the mold is a glove shape former. The coating composition includes a coagulant having the colloidal silica particles  
25 mixed therewith. The mixture of the coagulant and colloidal silica particles is applied to the surface of the glove former, which is dipped into the flowable elastomer and withdrawn, and the coagulated elastomer forms the matrix of the glove. The glove matrix is turned inside out, with the result that the outside surface has the plurality of colloidal silica particles thereon.  
30 Before it is turned inside out, the exposed surface of the glove matrix, which later becomes the inside surface of the glove, may be treated to improve handling characteristics and donnability with either powder-based or powder-free methods.

The present invention thus provides articles and a method for

5       producing articles that have a surface selectively covered with colloidal silica particles. Chemical or coating-type powder-free de-tackifying treatments to the inside surface of the glove, even where they also are applied to the outside surface, do not adversely affect the gripping enhancement of the silica particles on the outside surface of the glove. The gripping enhancement is based on the physical structure at the outside surface, not on chemical effects. The present approach therefore allows powder or powder-free treatments to be applied to the glove, enhancing manufacturability, shipping, and donnability, while simultaneously achieving excellent grip retention even when the glove is wet.

15       The particles are selectively present on the surface of the article to provide increased friction. In presently preferred applications, no other material in the form of a binder is used to bind the colloidal silica particles to the surface of the article. On the other hand, carefully chosen surface coatings may be used to achieve particular results. Examples are polyether or polyester polyurethanes and certain extensible acrylate-based copolymers. To enhance ESD properties other additives such as metal oxides, alkali metal salts such as lithium nitrate and polyethylene ether glycols may be employed. The colloidal silica particles are present only on the treated surfaces, and do not extend through the body or thickness of the matrix. If the colloidal silica particles were mixed through the entire thickness of the article, there would be a potential for adverse effects on the mechanical properties of the article due to the high volume fraction of particles present. The present approach selectively positions the particles on the surface of the article where they are required to increase friction and/or for electrical charge dissipation.

30       Other features and advantages of the present invention will be apparent from the following more detailed description of the preferred embodiment, taken in conjunction with the accompanying drawings, which illustrate, by way of example, the principles of the invention. The scope of

5 the invention is not, however, limited to this preferred embodiment.

### BRIEF DESCRIPTION OF THE DRAWINGS

10 Figure 1 is a perspective view of an article according to the invention, in this case a glove;

Figure 2 is a schematic enlarged sectional view through the matrix in the region of the palm of the glove of Figure 1, taken along lines 2-2;

Figure 3 is a schematic sectional view of a first embodiment of a silica particle;

15 Figure 4 is a schematic sectional view of a second embodiment of a silica particle; and

Figure 5 is a block flow diagram of a method for practicing the invention.

### DETAILED DESCRIPTION OF THE INVENTION

20 Figure 1 illustrates an article according to the invention, in this case a preferred glove 20. The present invention is applicable to other articles as well, and is not limited to the glove 20.

25 Figure 2 is a sectional view in the region of the palm of the glove 20, greatly enlarged to show the structures at the surfaces. The glove 20 is formed of an elastomer that is termed the "matrix" 22. The glove matrix 22 has an outside surface 24 and an inside surface 26. The inside surface 26 contacts wearer's hand when the glove 20 is in use, and the outside surface 24 faces outwardly to contact gripped articles.

30 A plurality of particles 28 are adhered to at least a portion of the outside surface 24. The particles 28 are preferably colloidal silica ( $\text{SiO}_2$ ) used in conjunction with the preferred manufacturing method to be described subsequently. Other types of particles, such as metal oxides

5 (e.g., aluminum oxide) or combinations of colloidal silica and metal oxides may be used as well. Because colloidal silica particles are preferred, the remainder of the detailed description will be directed toward their use, with the understanding that other types of particles may be used.

10 Preferably, at least a palm 30 and gripping portions 32 of the fingers 34 of the outside surface 24 of the glove 20 have the colloidal silica particles 28 affixed thereto. Other portions of the glove 20, such as the portion overlying the back of the hand, need not have the colloidal silica particles adhered thereto, but no harm is done if the colloidal silica particles are present on these other portions as well. In a typical manufacturing  
15 operation, the colloidal silica particles will be adhered over the entire outside surface of the glove 20.

The inside surface 26 may be either exposed elastomer of the matrix 22, as in region 36, or it may be treated, as in region 38. Treatments to the inside surface 24 in the treated region 38 typically would be directed toward  
20 reducing the tackiness during manufacture and storage, and/or improving the donnability of the glove 20, because the inside surface 26 contacts the hand of the wearer when the glove 20 is used. A number of de-tackifying and donnability treatments are available, such as polymer coatings, powders, chlorination, and chemical treatments. Such donnability  
25 treatments are known in the art. A virtue of the use of colloidal silica particles 28 on the outside surface 24 is that it permits the use of no treatment on the inside surface 26, or any of a wide variety of treatments of the inside surface 26, without the loss of effectiveness of either the colloidal silica particles 28 on the outside surface 24 or the selected  
30 treatment on the inside surface 26. The colloidal silica particles 28 are a physical element, not a surface treatment that may be eradicated or negated by the treatment of the inside surface 26.

Figure 3 illustrates one of the particles 28 in greater detail. The preferred particles are general spherical, with a maximum dimension

5 (diameter) preferably from about 10 nanometers to about 100 nanometers, although other sizes may be operable. The particles having a size range of from about 10 nanometers to about 100 nanometers have been employed most effectively in manufacturing prototype gloves. The particles 28 reside on the treated outside surface 24, and may be partially  
10 embedded into the outside surface 24 so that a portion protrudes above the outside surface 24. The colloidal silica particles 28 at the outside surface 24 of the glove 20 increase the friction between the outside surface 24 and an article being grasped by the hand of the wearer of the glove 20. The particles 28 are not easily removed by subsequent processing such as donnability treatment applied to the inside surface, nor are they readily  
15 removed by ordinary use of the glove. Consequently, the array of colloidal silica particles 28 provides a durable friction-enhancing physical feature on the outside surface 24.

The colloidal silica particles 28 do not extend throughout the entire  
20 thickness of the matrix 22. They are not incorporated throughout the matrix by mixing them into the flowable elastomer from which the matrix is made. This distinction is an important one, because a high fraction of colloidal silica particles distributed throughout the matrix, when they are needed only at the outside surface 24, may result in adverse effects on the physical  
25 properties of the glove, particularly its limit of extensibility in tension without failure. The colloidal silica particles 28 are present substantially only on the outside surface 24, not throughout the matrix. Occasional colloidal silica particles 28 may be present in the matrix as a result of the manufacturing operation, but they are not intentionally distributed throughout the matrix.

30 Figure 4 illustrates another type of colloidal silica particles 28. In this case, the particle 28 is made at least partially electrically conductive. In the pictured embodiment, the particles 28 have an electrically conductive surface treatment 44 applied thereto. An operable electrically conductive surface treatment 44 is the application of a thin layer of a metal or a metal-

5 containing substance such as aluminum chlorhydrate. Equivalently for the present purposes, the particles 28 could be made partially electrically conductive throughout, as by doping the silica that forms the particles 28 with a metal such as aluminum.

10 The use of electrically conductive particles 28 allows localized high levels of electrical charge, such as static charge or tribocharge, to be dissipated through conduction along particle-to-particle contacts. This electrostatic discharge (ESD) may be important in certain glove applications. For example, medical gloves may experience local charging for any of several reasons, and the local charging may adversely affect  
15 instruments or treatments. Gloves used in clean room facilities may also experience local charging, which may be transferred to the articles being manufactured or interfere with manufacturing operations, in either case adversely affecting the quality of the final product. The present approach provides for a reduction of locally high concentrations of static charge,  
20 eventually bleeding the charge to low, harmless levels. This reduction of static charge is accomplished without embedding wires in the glove matrix or other techniques that have been previously proposed but which interfere with the utilization of the glove in service or with its mechanical properties such as its extensibility. In a typical case, electrostatic decay times are  
25 reduced from 8-20 seconds to as low as 0.3 seconds with the approach of the invention, measured by the static decay test approach of Federal Test Method Standard 101C Method 4046. Specifications are listed in EIA-541, Mil B-81705C, and NFPA 99.

30 Figure 5 illustrates a preferred method for preparing an article, such as the glove 20, by the approach of the invention. A mold is provided, numeral 50. A surface of the mold defines at least a portion of the surface of the article to be manufactured, and in the preferred case defines the outside surface 24 of the glove 20. The mold for a glove is a shape of the human hand, known as a "former", made of glass, metal, porcelain, or other

5           suitable material.

          A coating composition is prepared, numeral 52. The coating composition includes the colloidal silica particles 28, mixed into a carrier which typically serves some other important function in the manufacture of the article. The colloidal silica particles are obtained commercially. Both  
10       untreated and electrically conductive colloidal silica particles are obtained from a vendor such as DuPont as Ludox<sup>R</sup> particles, or EKA Chemical as Bindzil<sup>R</sup> particles.

          In the preferred case, the carrier is a coagulant for the elastomeric composition that forms the matrix of the glove. (The carrier could be selected as a mold release agent in other applications.) A suitable  
15       coagulant is an aqueous solution of about 10-30 percent by weight calcium nitrate or calcium chloride, about 0.1-0.5 percent by weight nonionic, cationic, or amphoteric surfactant, and about 0.001-0.2 percent by weight silicone or non-silicone dewebbing agent. This coagulant is acidic with a  
20       pH of about 3.5-6.0, which requires the use of the acid-compatible colloidal silica rather than other forms of particles that are not acid compatible.

          The colloidal silica particles 28 are mixed into the carrier in a suitable loading, which is typically from about 0.1 to about 10 percent weight/weight for gloves. If a lesser amount of particles are used, they are largely  
25       ineffective. If a larger amount of particles are used, the surface of the elastomer becomes excessively tacky. The high tackiness is a disadvantage for gloves, but could be desirable for other products. Preferably, the loading of colloidal silica in the coagulant carrier is from about 0.5 to about 3.0 percent weight/weight. The resulting coating  
30       composition has a specific gravity of from about 1.18 to about 1.20, and a consistency like that of water.

          The coating composition is applied to the mold surface and allowed to dry in place, numeral 54. Coating is accomplished by dipping the former into the coagulant mixture and drying it in an oven.

5           A flowable elastomer is provided, numeral 56. This flowable elastomer forms the matrix of the glove after processing. The flowable elastomer is an elastomeric material in an appropriate solvent that allows it to flow. Suitable elastomers include any operable material, such as natural latex elastomer, or a synthetic elastomer, such as styrene butadiene, neoprene, isoprene, nitrile, styrene-ethylene-butylene-styrene (S-EB-S), styrene-isoprene-styrene(S-I-S), or styrene-polybutadiene-styrene(S-B-S) rubbers. This listing of suitable elastomers is exemplary, not exhaustive. Solvents for the various elastomers are known in the art.

10           The flowable elastomer is contacted to the mold which has been previously coated with the coating composition, numeral 58. In the case of the manufacture of a glove, the former is dipped into the flowable elastomer. Dip forming technology is well known in the art, and will be described only briefly. The coagulant in the coating composition causes some of the flowable elastomer to become locally unstable and coagulate onto the surface of the former. During this process, the elastomer coalesces, numeral 60, capturing the particles 28 present in the coating composition at the surface of the coagulating elastomer. The former is withdrawn from the mass of flowable elastomer, and the coagulated layer is allowed to coalesce fully. A coating or donning agent may be applied to the glove either before or after curing. Each dip typically applies from about 0.05 to about 0.20 millimeter of elastomer to the surface of the former, and the presently preferred approach utilizes a single dip. If a thicker layer of elastomer is required, the former is re-dipped to apply more elastomeric material. The elastomer is gelled with heat to strengthen the elastomeric film, leached with flowing hot water to remove impurities, and cured with heat to vulcanize, in the case of rubber, nitrile, and neoprene, and dry the film.

30           The now-solid layer of elastomer, forming the matrix 22, is separated from the mold, numeral 62. In the case of the glove, the elastomer is

5           turned inside-out when it is taken from the former, so that the portion of the glove initially contacting the former becomes its outside surface 24 with the colloidal silica particles 28 thereon. In the separation step 62, the colloidal silica particles serve as a functional replacement for powder as a release agent.

10           The article is optionally post-processed, numeral 64. The post processing may include further drying, chlorination, or other donnability treatments, for example. Such treatments are known in the art. The order of the separating step 62 and the post-processing step 64 may be reversed or the steps may be intermixed, so that some or all of the post-processing  
15           operations may be conducted with the glove still on the former, while some or all of the post-processing operations may be conducted with the glove removed from the former. As noted earlier, the post-processing operations have little effect on the silica particles affixed to the surface of the article.

20           The present invention has been successfully used to prepare gloves according to the preferred procedure discussed in relation to Figure 5, using three matrix compositions: natural latex, and nitrile and styrene-butadiene synthetic rubbers.

25           A polymeric donnability-enhancing layer was applied to the inside surface of the natural latex gloves. These gloves were measured to determine their powder levels according to the procedures of ASTM D6124-97. Measured powder levels were about 0.2-0.3 milligrams of powder per glove, well below the maximum of 2 milligrams of powder per glove established by the Food and Drug Administration for powder-free articles.  
30           This result is significant, because substantially none of the silica particles were dislodged from the surface and measured as powder. Gloves made according to the present approach therefore qualify as powder-free gloves, if a powder-free donnability enhancing treatment is applied to the inside surface of the glove. Protein levels in the absence of post processing were

5           less than 50 parts per million. The coefficient of friction of the outside surface of the glove treated with the silica particles was increased by about 50-65 percent compared to gloves treated by other processes such as chlorination to render them powder free.

10           Although a particular embodiment of the invention has been described in detail for purposes of illustration, various modifications and enhancements may be made without departing from the spirit and scope of the invention. Accordingly, the invention is not to be limited except as by the appended claims.

5

CLAIMS

What is claimed is:

10

1. A surface-modified glove article for use on a human hand, comprising:

an elastomeric matrix in the shape of a glove that receives the human hand therein, the matrix having an inside surface that contacts the human hand received within the hollow elastomeric glove shape, and an outside surface; and

15

a plurality of colloidal silica particles adhered to at least a portion of the outside surface of the matrix but not extending through the thickness of the matrix, the colloidal silica particles being affixed to the outside surface of the matrix.

20

2. The surface-modified article of claim 1, wherein the elastomer comprises natural latex.

25

3. The surface-modified article of claim 1, wherein the elastomer comprises a synthetic elastomer.

30

4. The surface-modified article of claim 1, wherein the elastomer comprises a nitrile rubber.

5. The surface-modified article of claim 1, wherein the colloidal silica particles have a maximum dimension of from about 10 nanometers to about 100 nanometers.

6. The surface-modified article of claim 1, wherein the colloidal

5 silica particles are electrically conductive.

7. The surface-modified article of claim 1, wherein the colloidal silica particles further comprise an electrically conductive surface treatment thereon.

10

8. The surface-modified article of claim 1, wherein the colloidal silica particles further comprise  
a layer of an electrically conductive material on the surface thereof.

15

9. The surface-modified article of claim 1, wherein the colloidal silica particles further comprise  
a layer of aluminum chlorhydrate on the surface thereon.

20

10. The surface-modified article of claim 1, further including a  
inside surface treatment on the inside surface of the glove shape.

11. The surface-modified article of claim 1, wherein there is no  
separate binder material affixing the colloidal silica particles to the outside  
surface.

25

12. A surface-modified article, comprising:  
an elastomeric matrix having a surface; and  
a plurality of colloidal silica particles adhered to at least a portion of  
the surface of the matrix but not extending through the thickness of the  
matrix, the colloidal silica particles being affixed to the surface of the matrix  
without any separate binder material affixing the colloidal silica particles to  
the surface.

30

13. The surface-modified article of claim 12, wherein the colloidal

5 silica particles are electrically conductive.

14. A method for making an elastomeric article, comprising the steps of : providing a mold whose surface defines at least a portion of the surface of the elastomeric article;  
10 preparing a coating composition comprising a plurality of colloidal silica particles;  
applying the coating composition to a surface of the mold;  
contacting a flowable elastomer to the coated surface of the mold;  
allowing the flowable elastomer to coalesce against the coated  
15 surface; and  
separating the coalesced elastomer from the mold surface.

15. The method of claim 14, wherein the elastomeric article is a glove.  
20

16. The method of claim 14, wherein the coating composition further comprises a coagulant.

17. The method of claim 14, wherein the flowable elastomer comprises natural latex.  
25

18. The method of claim 14, wherein the flowable elastomer comprises a synthetic elastomer.

19. The method of claim 14, wherein the flowable elastomer comprises a nitrile rubber.

Y	US 4 851 266 A (MOMOSE AKIRA ET AL) 25 July 1989 (1989-07-25) column 1, line 6 - line 10 column 1, line 15 - line 19 column 1, line 39 column 1, line 51 column 3, line 58 - line 65 column 5, line 31 - line 41 column 6, line 18	14-19

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

### \* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search

18 October 2000

Date of mailing of the international search report

26/10/2000

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2  
NL - 2280 HV Rijswijk  
Tel. (+31-70) 340-2040, Tx. 31 651 epo nl,  
Fax: (+31-70) 340-3016

Authorized officer

Monné, E
